Controlling Electrons, Spins, and Protons at Surfaces

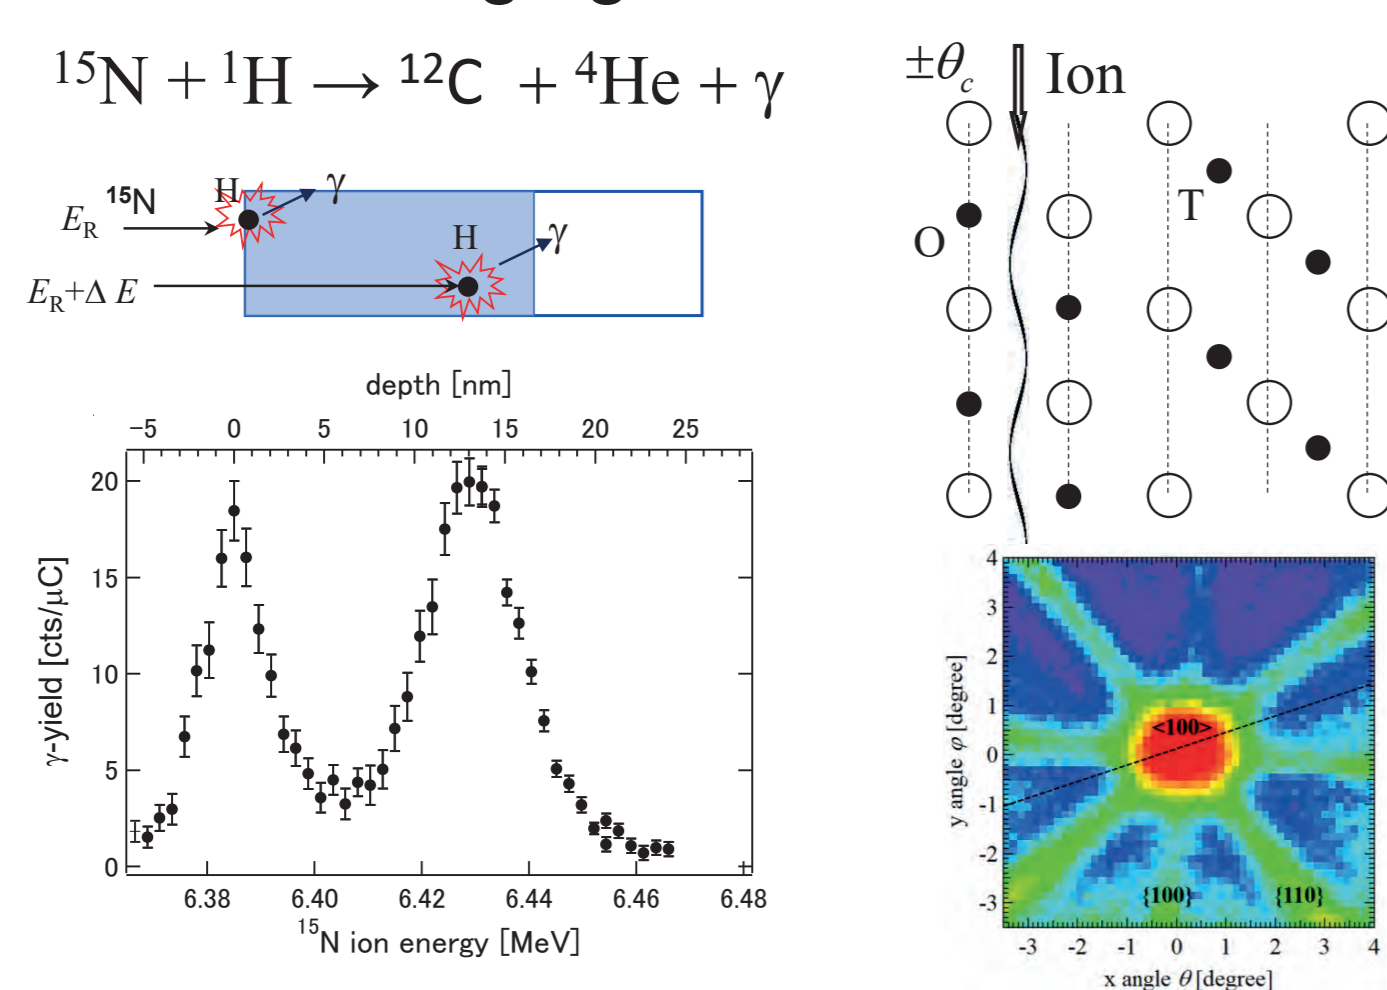

Overview

Surfaces and interfaces have different electronic states from those of bulk materials, because they have lower dimension and symmetry compared to the bulk. Thus, surfaces and interfaces are expected to reveal peculiar properties, such as interface electric conductivity and catalytic activities. From a technological point of view, surfaces play crucial roles in the formation, storage, and sensing of hydrogen that is a clean energy medium. In our laboratory, we develop novel experimental techniques to precisely observe hydrogen in aimed at elucidating the mechanisms of proton transport, electron dynamics, spin conversion and non-equilibrium hydrogenation of nm-thick metal/oxide films, which leads to synthesis of novel functional surfaces.

Experimental Techniques

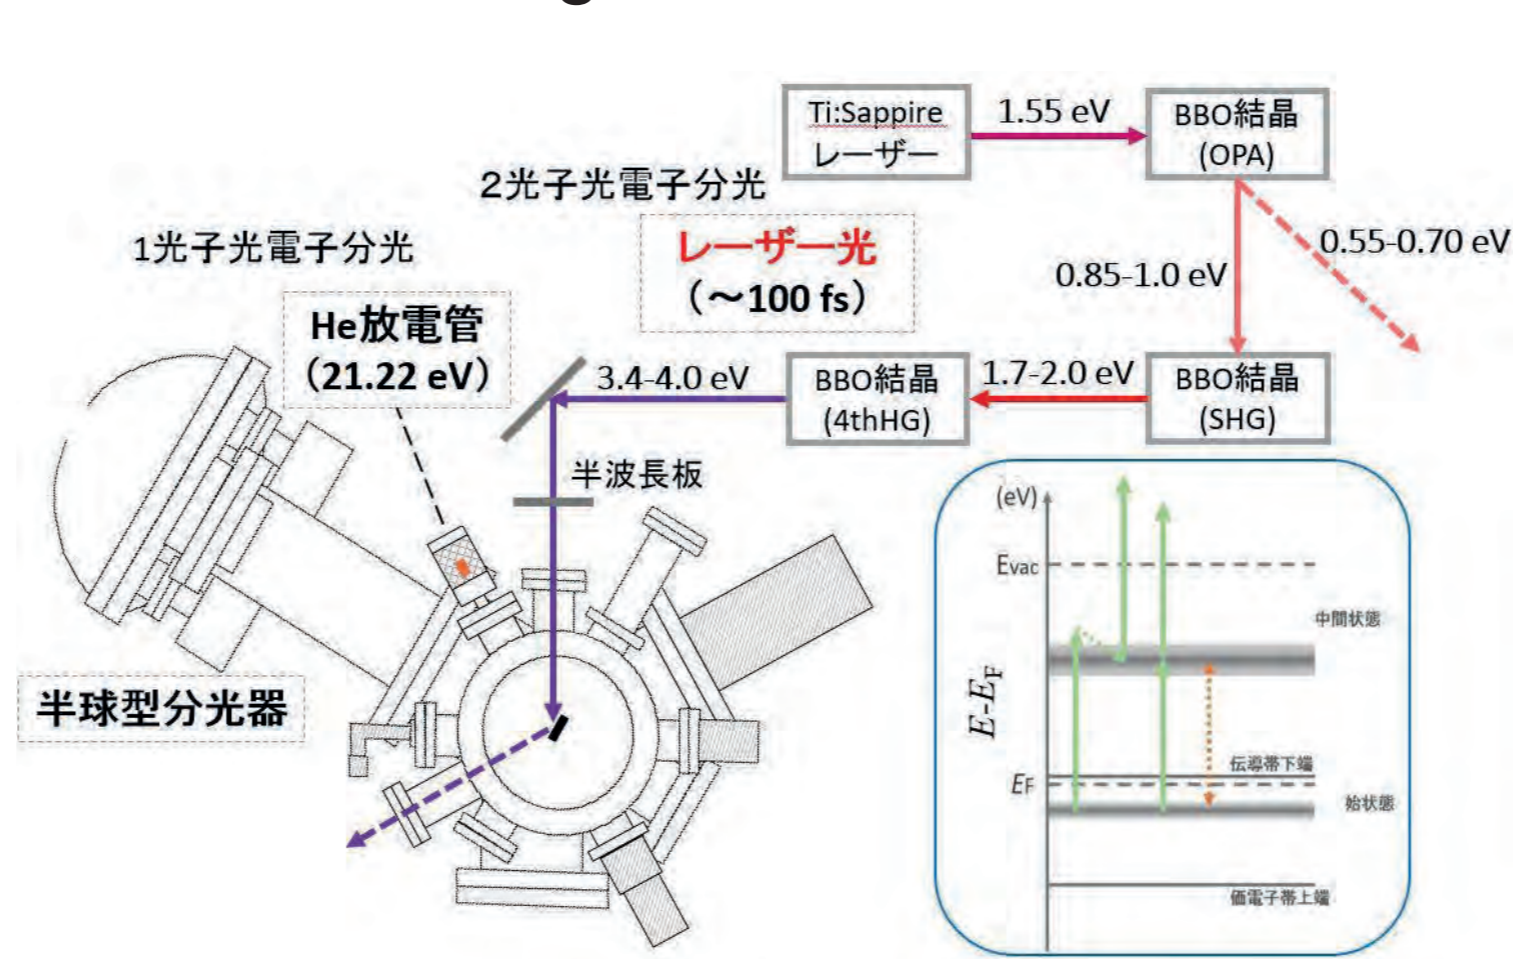

[Nuclear Reaction Analysis]

3D imaging of H in materials

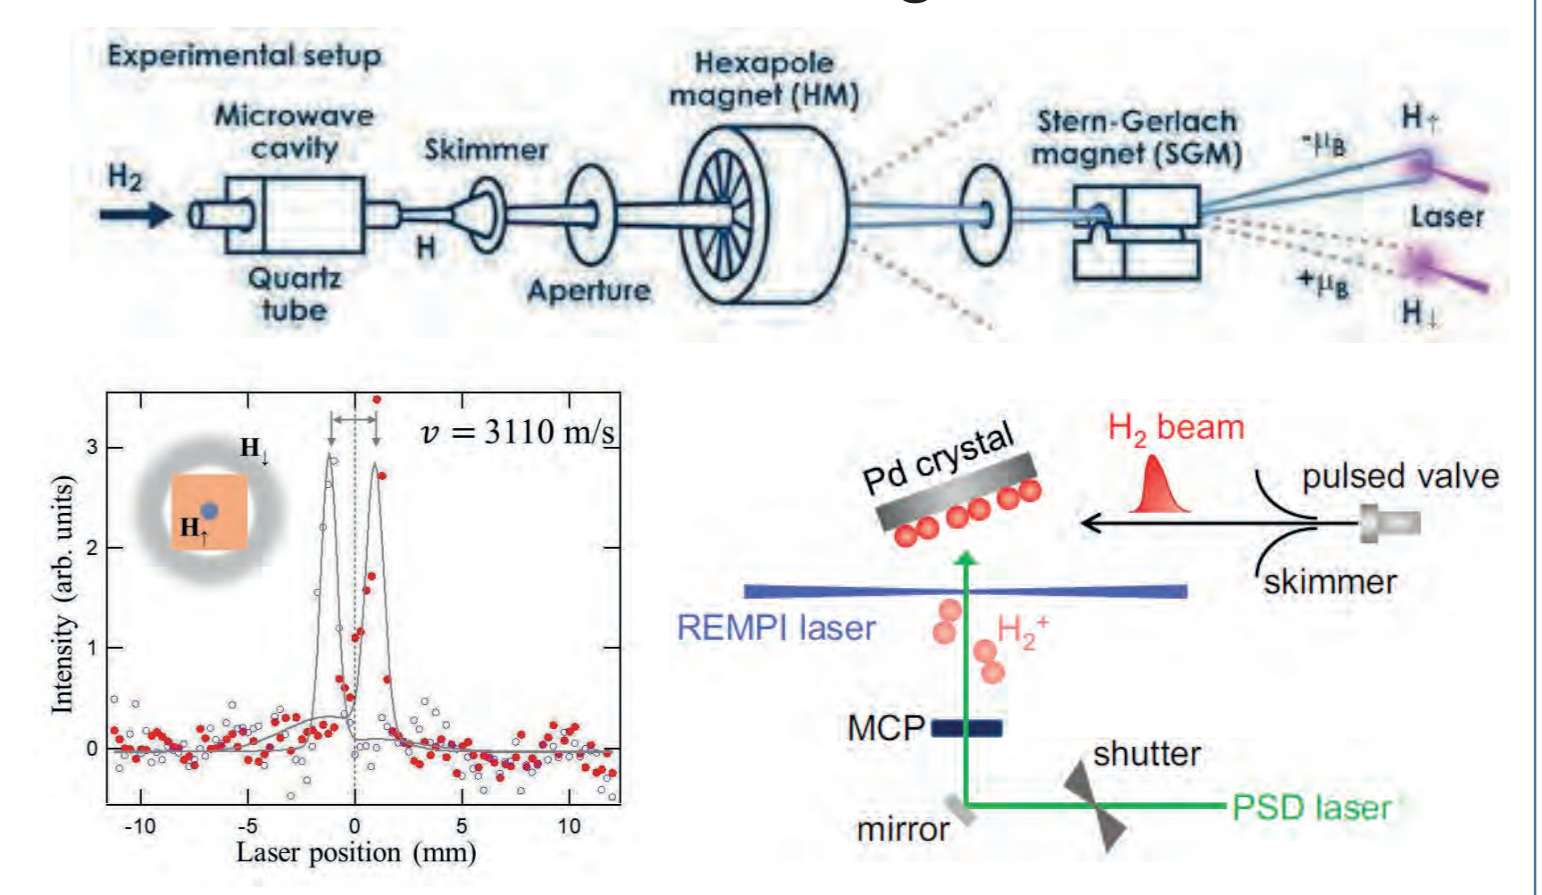

[(2-photon) Photoemission]

Electronic ground and excited states

[Spin-polarized H and Laser spectroscopy]

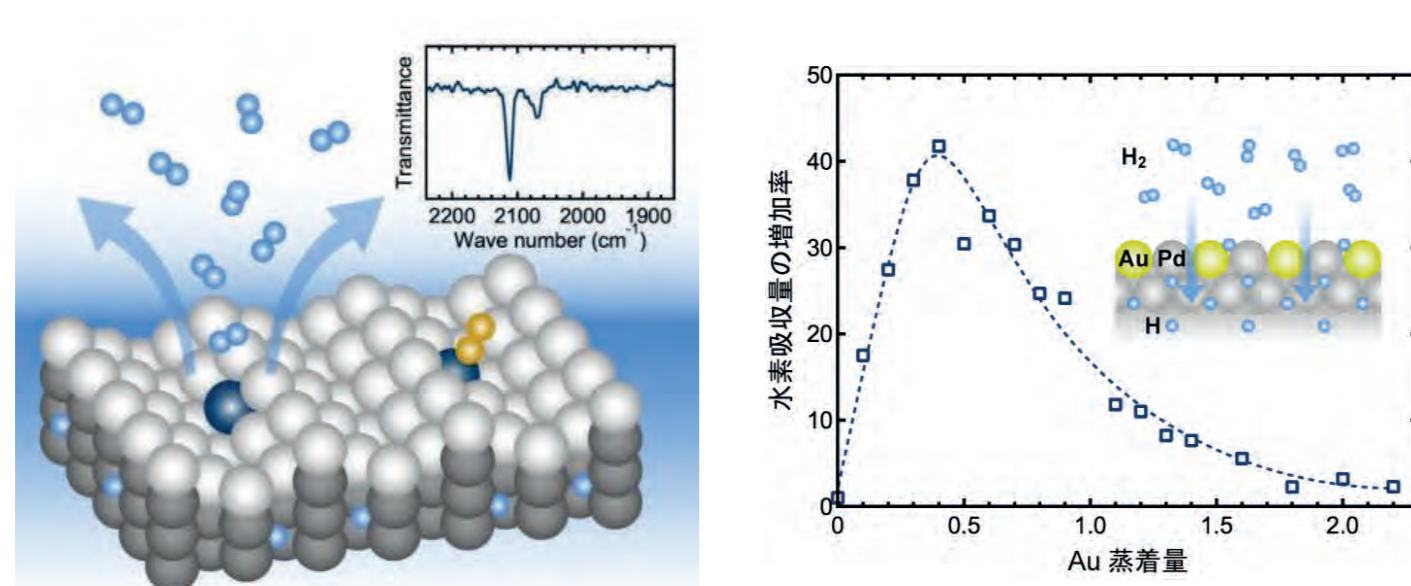

Spin conversion, rotational relaxation and surface magnetism

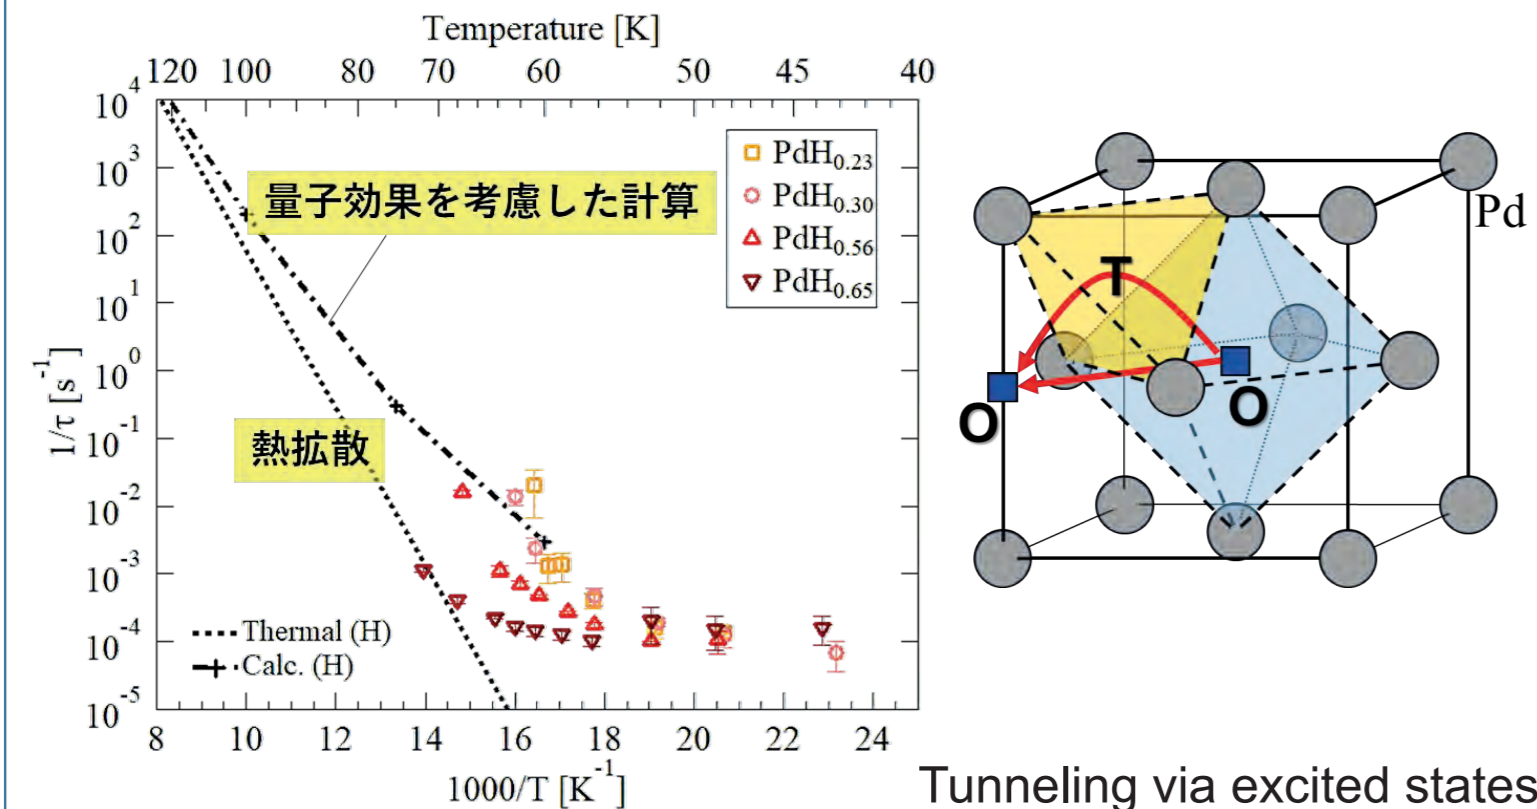

STM, Thermal desorption spectroscopy, Infrared absorption spectroscopy, etc.

Dynamics of protons, electrons, and spins

Control of H transport by surface modification

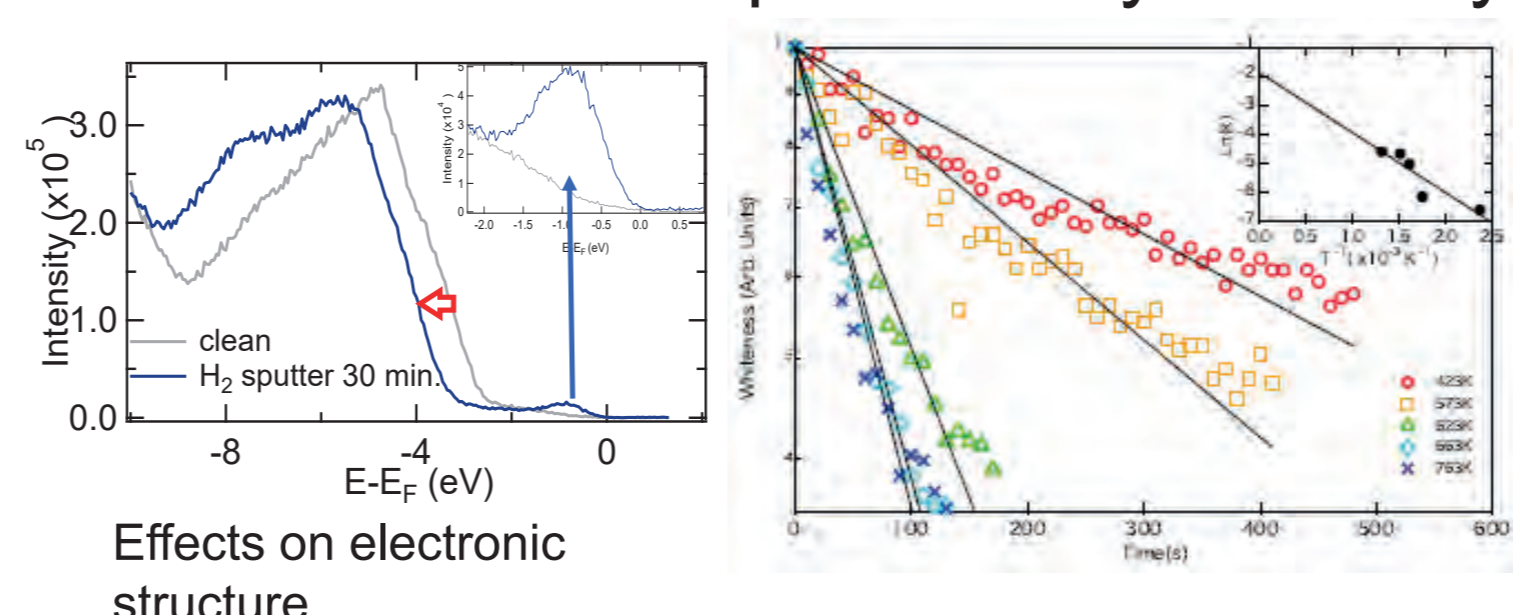

Quantum diffusion of H

Proton-electron separation and H diffusion at TiO2

Hydrogenation of TiO3 and photocatalytic activity

Hindered quantum rotation and nuclear-spin triplet-singlet transition
